PotKit

Invoices that pay you now.

Tokenise an unpaid invoice into tradeable shares on Portaldot V3, and pay every holder pro-rata, on-chain, when the debtor settles.

tPOT is testnet currency with no market value

THE PROBLEM

Waiting to be paid is slow, and small invoices are hard to fund.

Freelancers and small businesses

often have to wait to get paid after they deliver the work.

Factoring is closed

Opaque, manual, and not built for small invoices.

Investors cannot verify

No simple way to fund a slice of a receivable and be paid out automatically.

THE SOLUTION

One contract carries the whole receivable lifecycle.

1
Mint
The issuer records the invoice as an NFT receipt.

2
Lock
Terms are fixed and a fixed supply of shares is issued.

3
Trade
Shares are sold for tPOT on an escrow market.

4
Settle
The debtor pays at least the face value, in tPOT.

5
Claim
Every holder gets a pro-rata payout.

6
Redeem
The paid receipt returns to the issuer.

Payments use native tPOT: no stablecoin and no token approvals. Every step is a public transaction.

IT WORKS

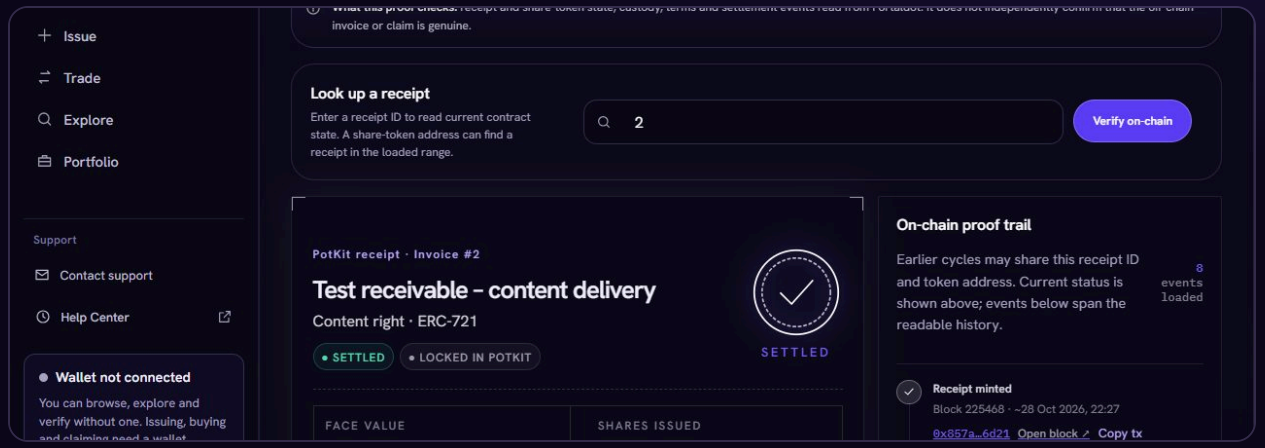

A full lifecycle, recorded on Portaldot V3 testnet.

STEP		BLOCK
Mint receipt #1	✓	97600
Lock, set terms, issue 100 shares	✓	97632
List 90 shares at 0.009 tPOT	✓	97654
Buy 90 shares for 0.81 tPOT	✓	97684
Debtor settles: pays 1 tPOT	✓	97706
Investor claims 0.9 tPOT	✓	97713
Issuer claims 0.1 tPOT	✓	97719
Redeem the paid receipt NFT	✓	97722

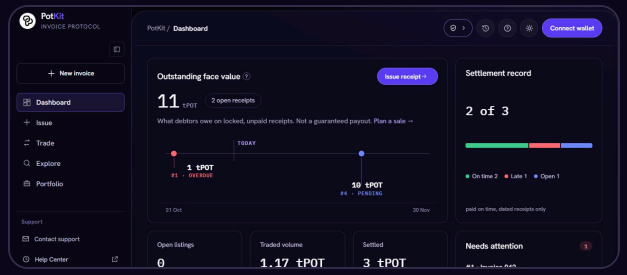

Contract `0x3c26…0fb7`, deployed 2026-10-19, block 97421. All 8 transactions succeeded.

Deploy tx `0x5ce8a4a4…bf41614` (community explorer Pindex).

VERIFY · RECEIPT #2, READ FROM THE CHAIN

DASHBOARD

EXPLORE

WHY PORTALDOT

Built for Portaldot V3, around its storage deposit.

- **EVM path (pallet-revive):** Solidity and Yul run as-is. ERC-721 receipts, ERC-20 shares.
- **Native tPOT settlement:** no stablecoin, no approvals.
- **Small on purpose:** one 3.9 KB contract, 82-byte share forwarders, reads run inside `eth_call`.

	FIRST DESIGN 4 CONTRACTS	POTKIT 1 CONTRACT
Deploy	1,386	327
Full demo	~87	~47

tPOT. Testnet estimates from `eth_estimateGas` (`scripts/measure.mjs`), not mainnet cost.

Not used today: WASM / ink!, cross-chain

ARCHITECTURE

No database: the chain is the source of truth.

Web app

React + viem, running in the browser. Reads and writes straight to the chain.

JSON-RPC

Portaldot V3 testnet

PotKit: one hand-written Yul contract (3.9 KB). Receipts, vault, settlement and market in one place.

Lens

Read logic that runs inside `eth_call`. Never deployed, so it costs no storage deposit.

Two small server functions

tokenURI JSON for receipts, and an optional faucet (closed for now).

Try it without tokens

Open the judge link: reading is free. To write, ask the Portaldot team for tPOT on Discord. Minting also needs the issuer's approval.

SAFETY AND HONESTY

Clear about what it proves, and what it does not.

ENFORCED ON-CHAIN

- Fixed share supply for each lock
- Settlement must cover the face value
- Payouts split pro-rata and empty the pool exactly
- 80 automated tests pass

NOT PROVEN

- Invoices are issuer-provided: PotKit does not verify them
- No on-chain debtor attestation (the optional signature is off-chain), no default or recovery procedure
- Payment is not guaranteed

What the product does about it: limits shown next to every action, a public Verify page, an optional off-chain debtor acknowledgement (a signature, not proof of identity), and an issuer payment record from on-chain events.

TRACTION, STATED HONESTLY

What exists today, read from the chain.

wallets, both the builder's

8 / 8

lifecycle steps recorded, from mint to redeem

Read from the kit's event logs on 2026-11-04. Testnet only. No customers, revenue or partners are claimed. Live app: app.potkit.pro. Open source (MIT).

A PLAN, NOT SHIPPED

Where PotKit goes next.

First users

Freelancers and small businesses with unpaid invoices, as issuers. Minting is permissioned, so they are approved one by one.

Earning

None today: no fee in the contract, and PotKit is open source. Near term: ecosystem support after the hackathon.

First channel

The Portaldot community. A tester sends an address, the issuer approves it, and the testnet transactions are the evidence.

Why now

Portaldot V3's new EVM path, and a design built around its storage deposit: deploy ~327 tPOT against 1,386.

Issuer-provided details are not verified; payment is not guaranteed. No market size or usage is claimed.

ROADMAP AND ASK

What comes next, and what support would unlock.

Roadmap

- Optional on-chain debtor acknowledge and dispute, and richer issuer reputation
- An explicit default and recovery policy
- Partial payments and instalments
- An indexer for history

Continued support would unlock

- Mainnet migration guidance
- RWA data mapping, oracle or data synchronisation
- A security review
- Liquidity and gas incentives
